Progression of Wound Healing and Patient Quality of Life with a New, 2 Layer Compression System*

Donna Walker, LPN and Terry Treadwell, MD, Institute for Advanced Wound Care at Baptist Hospital

Background

- Compression therapy is an essential element for managing edema associated with leg ulcers.
- Adequate treatment is effective at improving the quality of life of patients with venous ulcers.
- An ongoing challenge for clinicians is to meet patient-centered needs (comfort, ease of use, non-interference of functional activities) while adequately reducing edema to promote venous leg ulcer healing.
- Limitations of current compression devices negatively impact patient quality of life and treatment protocol adherence. These limitations include patient discomfort, product slippage, and overall dissatisfaction with the compression materials.

Case Study 1

55 Y/O male. Current ulceration present for 120 weeks. Located at a previous burn site. ABI 1.01. Patient adherent to compression, including Unna boot with elastic bandage and 4-layer system. No other medical conditions. 6’3” tall, 185 lb. Randomized to 4-layer on initiation.

- Wound area at Day 0 = 20.8 cm²
- Week 4: cross-over wound area = 16.5 cm²
- Week 8 wound area = 11.8 cm²

- Average 4-layer slippage = 4.3 cm/week
- Average 2-layer slippage = 2.7 cm/week
- Quality of Life attributes reported by patient to have improved while wearing the 2-layer system included less sleep disturbance, less pain from the wound site, and improved ability to perform daily living.

Case Study 2

50 Y/O male. Present for 50 weeks. ABI 1.0. Previous compression systems include Unna boot with elastic bandage and 3-layer system. Works as a manager 6 days/week in a shop and walks a lot. Randomized to 2-layer on initiation.

- Wound area at Day 0 = 11.8 cm²
- Week 4: cross-over wound area = 8.6 cm²
- Week 8 wound area = 6.1 cm²

- Average 4-layer slippage = 5.6 cm/week
- Average 2-layer slippage = 0.84 cm/week
- Patient very pleased and said that the 2-layer system was by far the most comfortable compression system that he’d ever been in. The wound made excellent progress.

Case Study 3

39 Y/O male. S/P with surgery 10 years ago. Present for 24 weeks with little healing progress, though patient adheres well to compression. Previous compression systems include 3 and 4-layer compression, and Unna boot with elastic bandage. Works long hours as barber. Walks everywhere. 6’ tall, weight 240 lb. ABI = 1.01. Randomized to 4-layer on initiation.

- Wound area at Day 0 = 5.0 cm²
- Week 9 wound area = 5.0 cm²

- 7 day wear of 4-layer. Mean slippage = 2.6 cm/week
- Patient very pleased and said that the 2-layer system was by far the most comfortable compression system that he’d ever been in. The wound made great progress.

Discussion

- As willing participants in a clinical trial, each subject adhered to the protocol and experienced wound healing progress due to effective, sustained compression.
- The 2-layer system was as effective as the 4-layer system in reducing edema and managing the clinical condition.
- QoL scores were difficult to interpret with only 3 subjects. Interpretation will require analysis of all 80 patient data.
- The 2-layer system provided these patients with comfortable compression and 7-day wear time with minimal slippage.
- Both the patients and clinician reported that the 2-layer system was faster to apply and remove which was appreciated in the busy clinic.

About the QoL Tool

Several validated tools* are available to assist clinicians and researchers in understanding how chronic wounds affect patients’ everyday life and their emotional response to these effects.

A quality of life tool, the Cardiff Wound Impact Schedule, has been developed specifically for patients with leg ulcers and diabetic foot ulcers. It measures Health Related Quality of Life as it relates to physical symptoms and everyday living. 3 scales are used: physical symptoms and everyday life, social life, and daily life (ability to get out and about), and well-being, including anxieties about their outcome.

This tool was selected to learn how product design and performance attributes affect a patient’s general reaction to their condition and treatment. Use of a QoL tool may assist clinicians in evaluating the effectiveness of a new technology.
