Performance under pressure.
Do more with 3M™ Glass Bubbles

Introduction

3M™ Glass Bubbles are a family of high-strength, low-density additives used in a variety of industrial applications. They are available in a wide range of densities and crush strengths, including our 3M™ Glass Bubbles iM Series, engineered to survive the rigors of compounding and injection molding. They offer excellent survivability at the high pressures encountered in typical plastics processing operations. The chemically stable soda-lime-borosilicate glass composition of 3M glass bubbles provides excellent water and oil resistance. Because of their spherical shape, glass bubbles behave like tiny ball bearings, causing them to flow within a liquid polymer much better than common mineral fillers. As a result, the impact on rheology (viscosity, melt-flow, etc.) is significantly less than the impact caused by mineral fillers. A benefit of this is the ability to form highly-filled parts and/or parts with more complex geometries more easily. This can mean lower mold temperatures and lower injection pressures than would be possible when molding polymers filled with mineral fillers. In addition, the spherical shape (aspect ratio of 1.0) often improves the dimensional stability of the polymer composite, resulting in less shrinkage and warpage.

3M glass bubbles are compatible with most common thermoplastics, including polypropylene, nylon, ABS and others.

Product Spotlight: 3M™ Glass Bubbles iM Series for Injection Molding

3M™ Glass Bubbles iM16K are the latest generation of high-strength glass microspheres, specially engineered for producing lightweight plastics. They feature an isostatic crush strength of 16,000 psi and a particle size of 20 microns. And with a density of just 0.46 g/cc, 3M Glass Bubbles iM16K can deliver weight reductions of 15% or more – without compromising strength or other physical properties. For higher pressure operations, 3M™ Glass Bubbles iM30K have a strength of 27,000 psi at a 0.60 g/cc density and a particle size of 18 microns.

Unlike irregularly-shaped fillers, 3M glass bubbles roll easily over one another. This helps increase volume loading capacity, reduce shrinkage, and lower resin demand. It can also help reduce warpage in many molded plastic parts.

Note: The purpose of these guidelines is to provide basic information to customers for use in evaluating and developing their own processes for compounding and injection molding using 3M glass bubbles. The information provided is general or summary in nature, and is offered to assist the customer. The information is not intended to replace the customer’s careful consideration of the unique circumstances and conditions involved in the use and processing of 3M glass bubbles and other products. The customer is responsible for determining whether this information is suitable and appropriate for the customer’s particular use and intended application.
Compounding

To compound polymers with 3M™ Glass Bubbles, 3M recommends the use of a compounding extruder, such as a twin-screw extruder or a BUSS Kneader, with a downstream feedport for adding the glass bubbles to the polymer melt. The extruder screw flights beyond this point should be set up to impart a minimum amount of shear stress. Distributive mixing elements, such as gear mixers, are preferred. Aggressive dispersive mixing elements, such as reverse flight elements and kneading blocks, are not recommended. Single screw extruders are generally not recommended because they typically do not have a downstream port and often contain “barrier” designs or other narrow tolerance/high shear features. A system designed for adding chopped fiberglass to a polymer would be a suitable starting point when developing a low shear extrusion system for glass bubbles.

Feeding

In order to minimize 3M glass bubble breakage, it is preferable to add the 3M glass bubbles downstream from where the polymer is melted, rather than into the feedport with the polymer pellets. An auger-driven side feeder at the downstream port, rather than a simple open hopper, will provide the most consistent feeding behavior. Although not as critical as feed location or method, it is further advisable to minimize extruder screw speed and to minimize extruder outlet pressure. 3M glass bubbles should be fed with an automated feeder. Although a volumetric feeder should produce satisfactory results, a gravimetric feeder – ideally one equipped with a twin shaft – is preferred. It is recommended that the 3M glass bubbles be supplied to the feeder automatically; for example, using an automated vacuum feed system with a pre-hopper. Like other fillers, 3M glass bubbles can entrain some air into the polymer during feeding and compounding. If entrained air in the final compounded pellets is undesirable, use a vacuum vent downstream of the 3M glass bubble feed port. Information on glass bubble handling can be found on pages 6-7.

Pelletizing

Any pelletizing method suitable for the polymer of choice is suitable for a system containing 3M glass bubbles. For plastics highly-filled with 3M glass bubbles, it might be advisable to use an underwater strand pelletizer or water slide pelletizer.

3M™ Glass Bubbles will become fluidized when aerated (which often occurs when initially filling a hopper) and this may lead to flooding of the hopper. To help prevent flooding, we recommend that the feeder discharge be covered until the hopper is filled with 3M glass bubbles. Upon filling, the 3M glass bubbles at the bottom will become de-aerated, and the feeder discharge may be uncovered in order to begin compounding. The hopper level should be maintained to at least 30% of its filled capacity, to help prevent flooding during operation.
Injection Molding

3M™ Glass Bubbles can be used with all high performance engineered thermoplastics, such as TPO, TPU, PBT, PEEK, PPS and nylon. Their high strength and spherical shape help minimize warpage and shrinkage, providing more control over finished part dimensions. This also gives them the ability to form highly-filled parts more easily, allowing lower mold temperatures and lower injection pressures.

Processing Start-Up

All thermoplastics require unique start-up conditions, depending upon the polymer grade and the supplier. Processing conditions do not typically need to be altered when using 3M glass bubbles. However, because the addition of 3M glass bubbles does change the viscoelastic properties of the polymer, 3M recommends considering the following:

1. Slightly reduce the usual fill and screw speeds. At higher loading percentages, these speeds may need to be reduced even further.
2. Set the temperature at the upper end of the operating range in all zones.

Experimentation to optimize results is recommended.

| Melt on high end of polymer supplier’s recommended settings to lower viscosity |
| Use 1.5 in. (38 mm) diameter or larger screws |
| During filling, packing and holding stages, keep actual injection pressure* below the isostatic crush strength of the given 3M glass bubble product (see page 2). |
| On end of screw, use non-restrictive, free-flow check ring |

* Use intensification factor to calculate actual injection pressure – see page 5.

Figure 2. Equipment Recommendations
trapezoidal runners, which do not require special alignment features (like the full round runners) can also be used. The cross-sectional area of the modified trapezoidal runner should be the same as a full round runner, which is 0.5 square inches (322.6 mm²).

The sprue used for processing 3M™ Glass Bubbles should be short, having a radius of 0.125 inches (3.17 mm) towards the nozzle, which is then tapered to 0.172 inches (4.37 mm) at the other end.

3M recommends using end-gated and/or fan-gated designs. Direct gating, with high injection pressures, can cause excessive bubble breakage. A minimum gate thickness of 0.06 inches (1.5 mm) should be used.

3M recommends the following:
- For long production molds, use tool steel hardened to Rockwell C-60+; for example, 4-20SS, S-7, H-13.
- Vent cavities at the end of the fill to minimize trapped gasses.
- Use largest-possible size gates.
- Reduce injection speeds.
- Machining marks can increase wear. A 4 microinch (.0001 mm) or better finish is recommended. Mold plating can also extend mold service life.
- Fan or parallel, edge gated designs have shown less bubble breakage, compared to direct gated designs.
- During filling, packing and holding stages, keep actual injection pressure* below the isostatic crush strength of the given 3M glass bubble (see page 2).
- Use intensification factor to calculate actual injection pressure – see page 5.

Some resin systems can be sensitive or degraded by the presence of the glass bubbles. The glass bubbles are pH basic and can react with PC and PC blends (PC/ABS), Polyester and some Fluoroplastics. Please contact your 3M representative for applications in these resins.

Temperature Settings
Compounds containing high loadings (>20 vol%) of 3M glass bubbles typically require higher mold temperatures than unfilled polymers. Melt on the high end of the polymer supplier’s recommended temperature settings, to help lower viscosity and achieve a smoother, blemish-free surface.

### Troubleshooting

<table>
<thead>
<tr>
<th>Problem</th>
<th>Possible Cause</th>
<th>Possible Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Increased part density (higher than theoretical)</td>
<td>Excess 3M glass bubble breakage</td>
<td>Reduce melt pressure during mold filling and packing stages</td>
</tr>
<tr>
<td>Mold not completely filled (“short shot”)</td>
<td>Viscosity increase caused by addition of 3M glass bubbles</td>
<td>Increase mold temperature</td>
</tr>
<tr>
<td>Surface Defects</td>
<td>Viscosity change; non-uniform dispersion of 3M glass bubbles</td>
<td>Reduce injection speeds and/or increase mold temperature</td>
</tr>
</tbody>

Visit 3M.com/glassbubbles to download technical papers for more information on processing considerations, including: twin screw extruder configurations; the effect of processing conditions on glass bubble survival; discharging and transferring glass bubbles, and more.
Regrinding
Regrinding creates the potential for excessive glass bubble breakage, which can result in loss of desired physical properties of the polymer. It is recommended that regrind be mixed with adequate quantities of virgin pellets, and part testing be performed to ensure desired results are achieved.

Handling
For guidance unloading 3M™ Glass Bubbles from their packaging reference our detailed handling guides:

- 3M™ Glass Bubbles Bag Unloading Suggestions
- 3M™ Glass Bubbles Box Unloading Instructions

Product Storage
Ideal storage conditions include unopened cartons in a dry and temperature-controlled warehouse. Extended exposure of 3M glass bubbles boxes to high humidity and/or conditions susceptible to condensation may result in some amount of “caking” of the glass bubbles. To minimize the potential for caking and thereby maximize storage life, the following suggestions are offered:

1. Carefully re-tie opened bags immediately after use.
2. If the polyethylene bag is punctured during shipping or handling, seal the hole as soon as possible or insert the contents into an undamaged bag.
3. During hot and/or humid months, store boxes in the driest, coolest space available.

If controlled storage conditions are unavailable, carry a minimum inventory, and process on a first in/first out basis.

Product Handling & Safety
Handling: Due to the low weight and small particle size of 3M™ Glass Bubbles, dusting may occur while handling and processing. To minimize the dusting potential during handling, consider the following:

- Do not open 3M glass bubbles packages until ready to use.
- Upon opening, have an air siphon near the opening to pull away airborne particles. (Dust collection equipment may be required – check local OSHA and other applicable regulations.)

- Remove 3M glass bubbles with a suction “wand” (with slight positive pressure aeration) and transfer to a closed mixing tank inside fully contained piping. If a closed mixing tank is not available, use dust collection equipment as close as practical to the point of entry. Pneumatic conveyor systems have been used successfully to transport glass bubbles without dusting from shipping containers to batch mixing equipment. Equipment vendors should be consulted for recommendations.

- Static eliminators should be used to prevent static buildup.

Safety: For worker protection, please consider the following

- Use safety glasses with side shields for eye protection.
- An air-purifying respirator suitable for particulates may be selected for protection after an optional exposure assessment is performed for your specific application. (For additional information about personal protective equipment, refer to the product Safety Data Sheet.)

- Use with appropriate local exhaust ventilation/dust collection in the work area.

Refer to the 3M glass bubbles Safety Data Sheet for additional safety information

Additional Information
3M glass bubbles are supported by global sales, technical and customer service resources, with fully-staffed technical service laboratories in the U.S., Europe, Japan, Latin America and Southeast Asia. Users benefit from 3M’s broad technology base and continuing attention to product development, performance, safety and environmental issues.
