How does the 3M™ Bair Hugger™ Temperature Monitoring Patient Sensor measure deep tissue body temperature?

The 3M™ Bair Hugger™ Temperature Monitoring System uses a technique known as zero-heat flux thermometry to measure the temperature of the tissue beneath the sensor. The sensor creates a layer of “perfect insulation” which prevents heat from escaping the body, thus preventing heat loss from the tissue beneath the sensor. This condition enables an isothermal tunnel to form, allowing the temperature on the skin surface beneath the sensor to rise until it is equivalent to the deep tissue body temperature.

How closely does the Bair Hugger temperature monitoring system agree with other temperature monitoring devices?

The Bair Hugger temperature monitoring system provides measurement of deep tissue body temperature, which, when measured at the lateral forehead, produces a clinically-acceptable agreement with gold-standard estimates of core temperature (which are typically invasive type monitors). See the results of our clinical trials showing the average difference between the PA catheter and the Bair Hugger system is 0.2°C.

What clinical evidence is there to show the Bair Hugger sensor works?

3M has conducted two clinical trials of the Bair Hugger temperature monitoring system in cardiac and general hospital patients. The cardiac study showed that the 3M temperature monitoring system was in agreement with the PA catheter by 0.2°C.

Can the Bair Hugger sensor be removed and reapplied to the patient after initial placement?

The sensor is designed to be used once on a single patient and then discarded. Reattachment of the sensor may result in unreliable performance.
How should the skin be prepped for the 3M™ Bair Hugger™ Temperature Monitoring Patient Sensor?
The skin at the target site should be clean and free of lesions or sunburn. An alcohol wipe should be used to clean surface oils from the skin, but the skin should be completely dry prior to placing the sensor.

What should I do if my patient has adhesive allergies or sensitivities?
The medical-grade adhesive has undergone extensive biocompatibility testing that confirms its safety on humans. Moreover, none of the subjects in the clinical trials exhibited signs of a skin reaction to the adhesive. For patients with known atopy, the clinician should weigh the potential benefits of continuous deep tissue body temperature monitoring with the 3M™ Bair Hugger™ Temperature Monitoring System against the potential for producing an allergic skin reaction.

Is the sensor affected by moisture on the skin or the effects of moisture from a fever?
To date, there have been no indications that diaphoresis affects the reliability of the temperature reported by the Bair Hugger temperature monitoring system.

How does the Bair Hugger sensor capture data?
Each sensor is embedded with a flex circuit that contains a memory chip. The average temperature at the end of every five-minute increment is written to the sensor’s memory for two hours – always displaying on the control unit the last two hours of data. If the sensor is disconnected, regardless of the length of time, this will be indicated on the display as a missing bar on the trend line.

What happens to the trend data display if the procedure goes past two hours?
The trend data will always show the last two hours of patient temperature data.

Is the Bair Hugger sensor latex free?
The Bair Hugger sensor is not constructed with natural latex rubber components.

Are there any restrictions on the use of the Bair Hugger temperature monitoring system?
The Bair Hugger sensor should not be placed on damaged or compromised skin. Avoid using the sensor when there is a risk of skin preparation solutions or other fluids coming into contact with the temperature monitoring sensor (e.g. facial surgery, craniotomy).

What should be done if the Bair Hugger sensor comes off the patient?
The best option is to place a new Bair Hugger sensor on the patient to make sure the adhesive is sufficient and that the electronics have not been damaged in the sensor.

Is the Bair Hugger sensor reusable?
No. The Bair Hugger sensor is disposable and designed for single patient use only.
Does the unit or system alarm for any reason?  
Any software and hardware errors that may occur are indicated on the control monitor screen. 3M™ Bair Hugger™ Temperature Monitoring System does not contain an audible alarm.

How do we clean the 3M™ Bair Hugger™ Temperature Monitoring Patient Sensor cable?  
The sensor cable should be cleaned with an approved cleaner. See the operator’s manual for more information on cleaning.

Is the Bair Hugger temperature monitoring system compatible with diagnostic equipment like x-ray or MRI equipment?  
The Bair Hugger sensor is not x-ray transparent, so it should be removed if radiographs or CT scans of the head are needed. The Bair Hugger sensor must be removed before an MRI procedure, as it is not MRI-safe.

Is the Bair Hugger temperature monitoring system compatible with existing patient monitors in the OR, PACU or pre-op?  
Yes. The Bair Hugger system emulates the resistance response of a standard YSI-400 temperature sensor. The emulation cables can connect to either a standard ¼ or ⅛ inch phone jack.

Does the Bair Hugger temperature monitoring system read temperature in Celsius and Fahrenheit?  
The Bair Hugger system can display temperatures in either Celsius or Fahrenheit. There is a toggle on the back of the unit that allows the unit to switch back and forth between Celsius and Fahrenheit, however, the trend data display is always in Celsius.

How is the trend data shown on the screen populated with information from the patient?  
The average temperature of the preceding five-minute interval is written to memory on the sensor. The capacity of the memory display is two hours.
