# Navigating the Challenges in Battery Safety Testing For Materials Development and the Parallels With the Catalytic Converter

Brandon Bartling and Mark Fairbanks

# Parallels Between Emission Device Testing and Battery Pack Testing

Regulated global standards and validation protocols are based on complete systems

- Slow
- Costly
- Unrealistic for materials development use

ICE/Emission System

US EPA, CARB  
EURO 1–5  
China  
OEM Validation, Durability

EV/Battery System

UNECE R100  
GB 38031  
SAE J2464  
SAE J2929

# Parallels Between Emission Device Testing and Battery Pack Testing

## Early emission component durability challenges...

- Industry recognized gap in testing validation rigor
- Recognition that current tests weren't effective – not reproducing field failure modes
- Recognition the industry didn't understand material failure modes
- Collection of field data showed real-life conditions
- Equipment that made alternate testing possible
- Application specific test samples (availability)
- Need to produce tests results in shorter amount of time

# Parallels Between Emission Device Testing and Battery Pack Testing

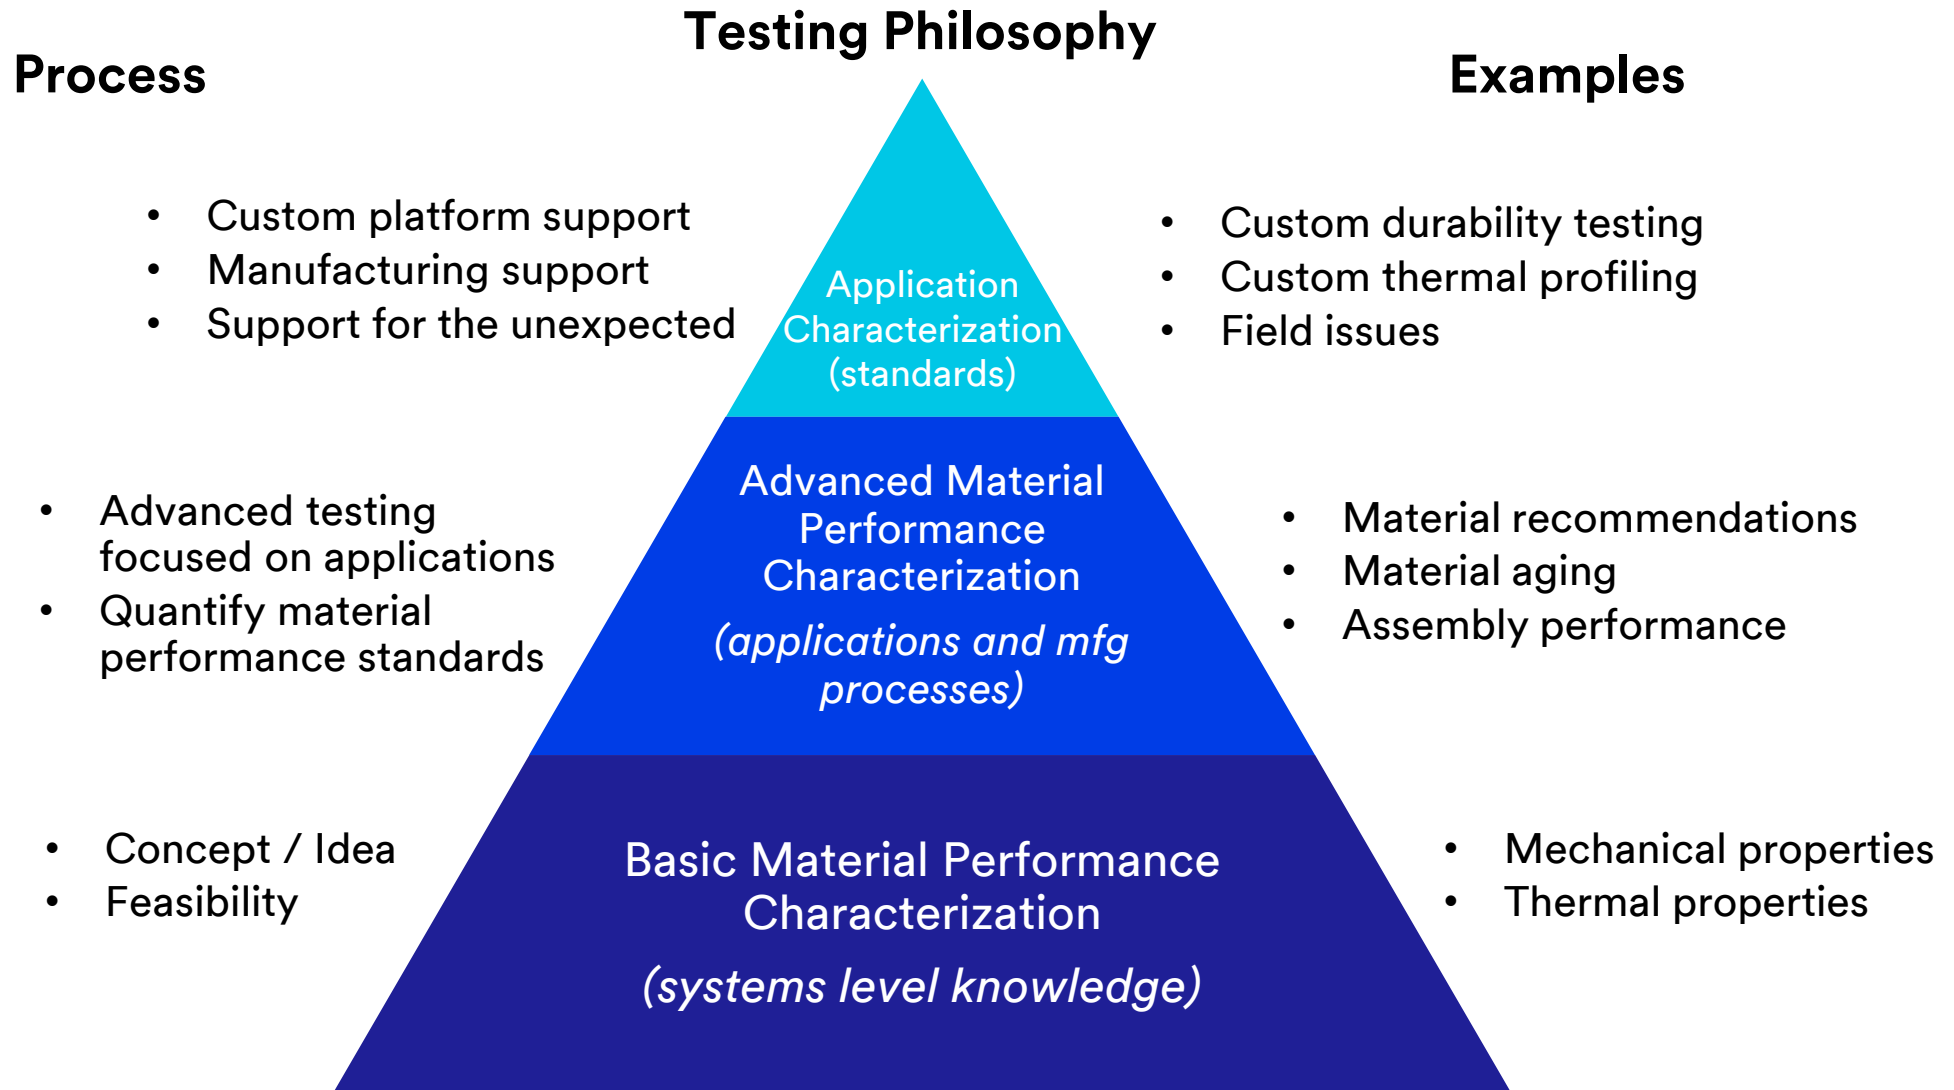

## Materials and component development

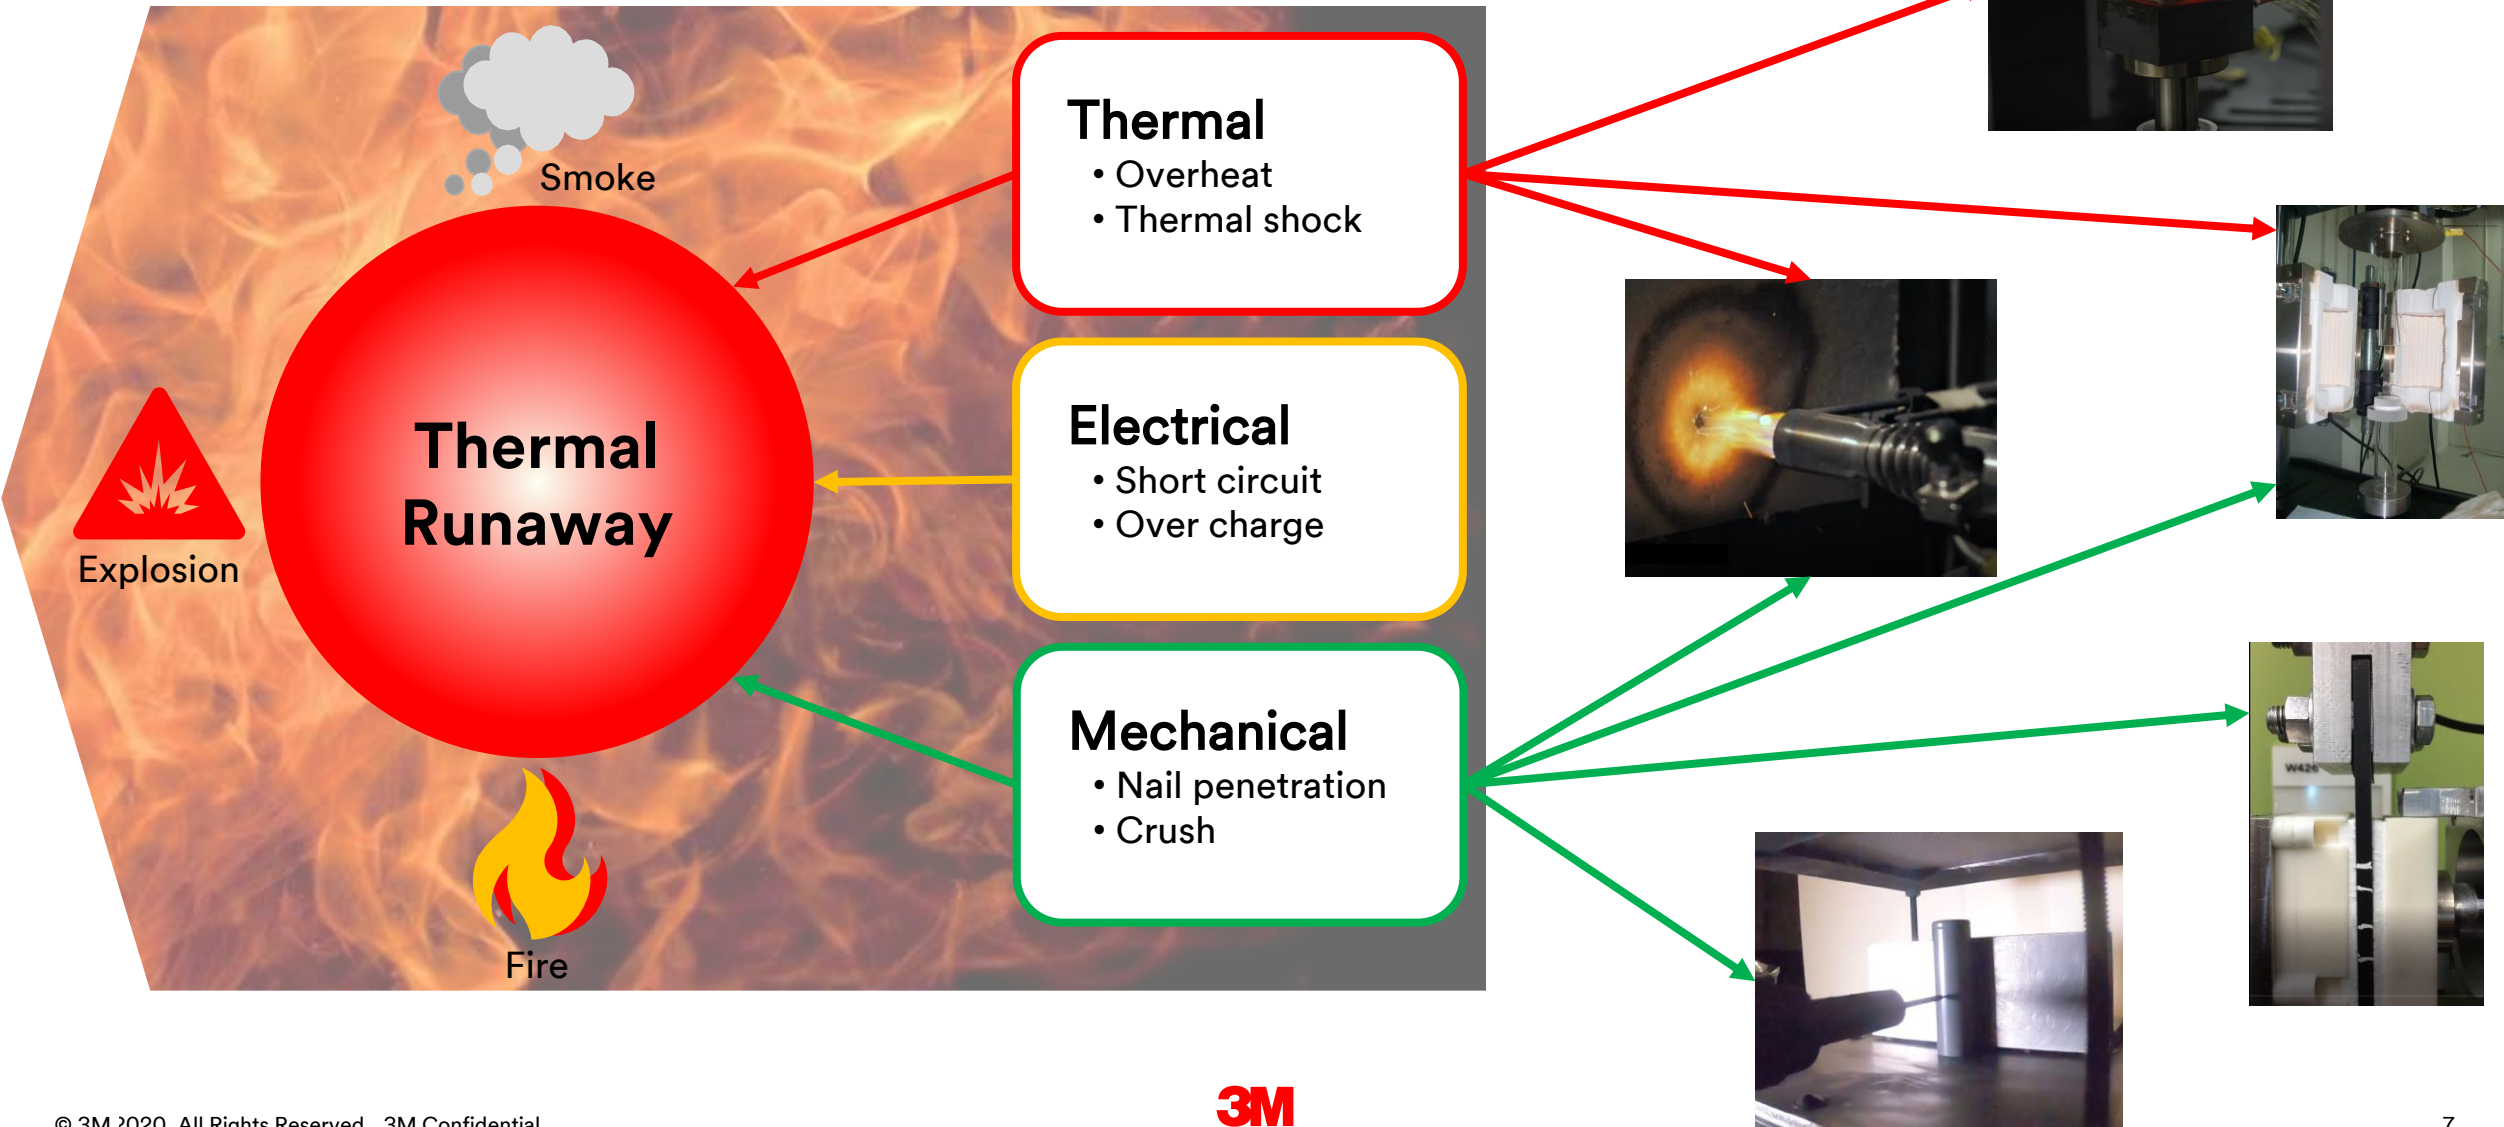

- Screening of materials
- Test methods that mimic real life situations
- Unspecific to individual OEM/Tier requirements
- Correlate test data to real life applications

# Parallels Between Emission Device Testing and Battery Pack Testing

# Development of Material Screening Tests

# Development of Material Screening Tests

Understanding heat flux  
and insulation properties

Understanding heat,  
pressure and media blast  
resistance

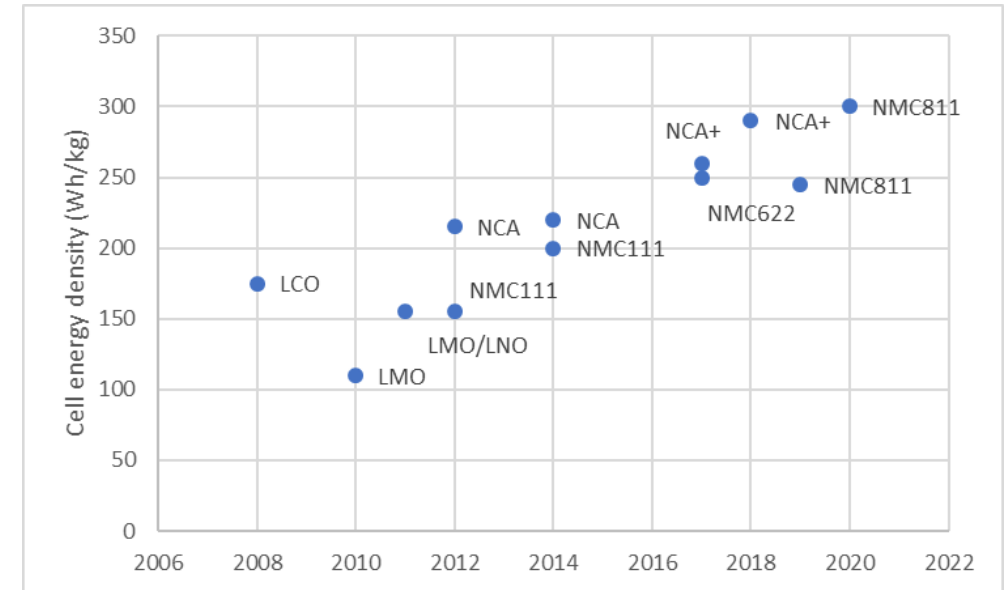

# Safety Challenges in Li-ion Battery Packs

- Cell and pack energy densities have continued to increase with the introduction of new chemistries
- New regulations are highlighting the need for a more focused understanding of battery safety
- Without a deep understanding of the pain points the solution may cause greater damage than good
- Battery safety must be thought of on the system level with different elements working to achieve the goal

Module Level

3X energy density increase in ~10yrs

# Methods of Thermal Runaway Initiation

The method of initiation can result in substantial differences in behavior. Defined methods of initiation include:

- **Nail penetration**
  - Steel 3-8mm diameter with 20-60° tip
  - Inserted from 1-10 mm/s in triggerable location
- **Thermal Initiation**
  - Heated coil or platen matched to cell energy
  - Energy provided by external source or the cell
  - Some standards include two separate tests
- **Overcharge**
  - A given amount of energy is inputted into the system
  - Electrical behavior of the cell is monitored vs. time

Nail used in thermal runaway testing

TRIM heater pioneered by NRC

Example of overcharge cell behavior

# Tradeoffs in Methods of Initiation

## Nail Penetration

- Method shows good repeatability and can be applied to all cell formats
- Accessibility, new failure modes and applicability can be a challenge

## Thermal

- Flexible form factor – emulates adjacent cell or external heat source
- Need to balance heat input – can be limiting to some cell formats

## Overcharge

- Emulates conditions where SOC has slipped
- Complicated by CID and other safety measures

Nail induced side wall eruption

Thermal initiated runaway resulting in melted containers

# Potential Pain Points Experienced During Thermal Runaway

There are several potential issues that can occur when a cell goes into thermal runaway.

Understanding the what will significantly help in addressing the how.

Large directed flames

Rapid high temperatures

Vent direction

Hot conductive particles

Smoke & particulate generation

Expansion

# Mechanically Related Challenges During an Event

Volume expansion

Emitted particle-based erosion

Deflagration & pressurization

## Component expansion

- Large format cells can experience non-symmetric expansion that can exceed >200% original volumes
- Forces >2MPa can be developed within the stack, which can lead to substantial damage to internal components

## Erosion

- 10-100 $\mu$ m particles are ejected from the cell during runaway
- The particles – in combination with the heat – result in mechanical abrasion of protective coatings and layers

## Gas pressure

- Greater than 8L per cell can be released during an event over seconds of release.
- Rapid release can fail seals, over-pressurize the pack and destroy mechanical systems

# Thermally Related Challenges During an Event

## Rapid heating of cells

- Once initiated cell temperatures can rise at rates  $>40^{\circ}\text{C}/\text{sec}$  to over  $1000^{\circ}\text{C}$
- Measured heat fluxes of  $>40\text{kW}/\text{m}^2$  peak released energy

## Thermal propagation (cascade thermal runaway)

- 10-100 $\mu\text{m}$  particles are ejected from the cell during runaway
- The particles – in combination with the heat – result in mechanical abrasion of protective coatings and layers

## Venting location

- Prismatic and cylindrical cells contain integrated vents to help guide the direction of failure
- Due to potential issues cells can vent in non-standard direction which expose adjacent cells to a direct blast

Successive cell failures

Non-optimum flame release

# Electrically Related Challenges During an Event

## Short-circuits due to component sag

- Aluminum – with a melting point of 660°C – is used in several pack components, including lids and busbars
- In the exposed temperatures energized component can warp and sag leading to shorting and electrically induced runaway

Electric components sag under heat

## Loss of component isolation

- Polymeric films (PET) are typically used to electrically isolate cells
- These films are unable to maintain isolation at these high temperature and allow for cell to cell shorting

## Electrically conductive hot debris

- Particles with temperatures  $>1200^{\circ}\text{C}$  can be ejected from the cell onto the surrounding components.
- The electrically conductive particles can burn through insulation and initiate electrical failure

Conductive debris

Molten cell containers allow for cell to cell shorting

# Chemical Related Challenges During an Event

Smoke formation prior to combustion

## Chemical Release

- Gas released from a cell during runaway can contain a mixture of CO, CO<sub>2</sub>, H<sub>2</sub>, HF and C<sub>x</sub>H<sub>y</sub> in cell dependent ratios
- Improper venting that inhibits the release of these gases in the pack can lead to gas levels above allowable limits
- Understanding of the relationship between gas composition, SOC and cathode types still continues

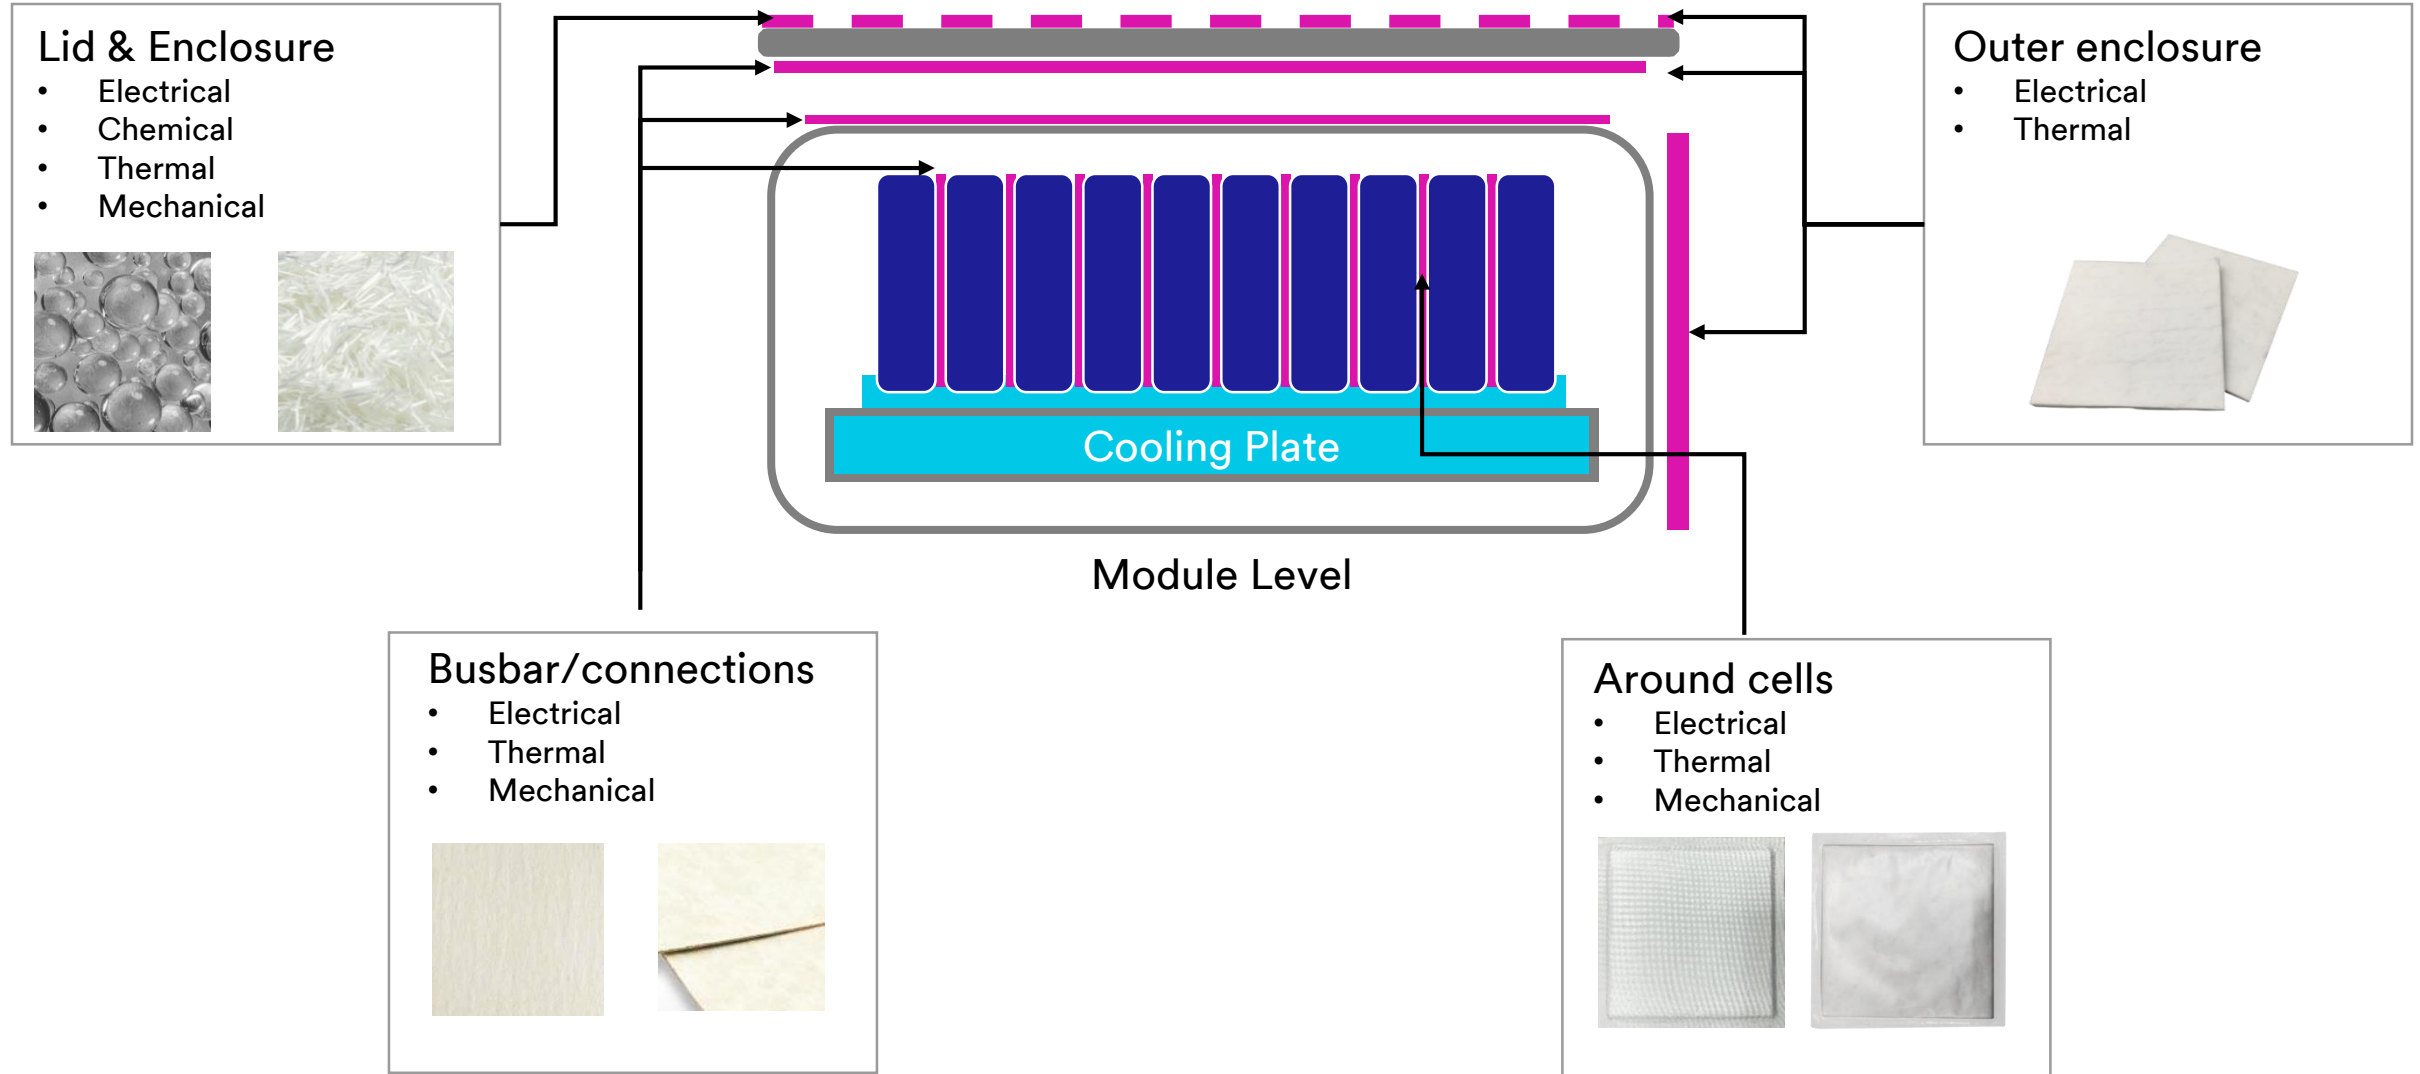

Micro-combustion calorimetry (Safronova 2019)

## Smoke and particles

- Materials used in the construction of the battery pack can serve as fuel during thermal propagation
- Release of harmful species and incompletely combusted materials need to be considered
- Methods can be used to assess the rate of heat release of material and their contribution to smoke generation

# Tackling the Battery Safety Problem

# Mechanical Material Properties to Address the Need

## Higher Strength-Focused Features

- High thermal runaway durability (blast)
- High temperature resistant (> 1200°C)
- Flexible
- Material thickness: 1.0 mm – 2.0 mm
- Basis weight: 1.5 to 2 kg / sqm

Condition after 12<sup>th</sup> blast

## Electrical-and-Flexibility-Focused Features

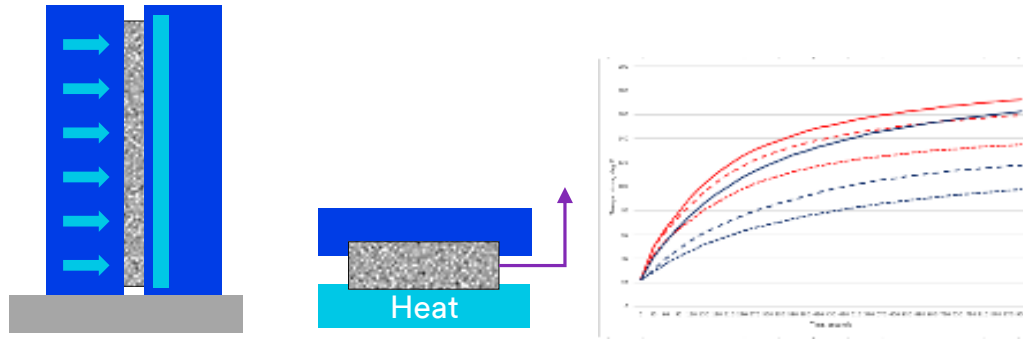

- High temperature resistant up to 2000°C
- Dielectric strength > 5.8 kV
- 3D-formable
- Material thickness: 1.0 mm – 2.0 mm
- Basis weight: 1 to 1.5 kg / sqm

Materials can be highly conformable with tradeoffs

# Thermal Material Properties to Address the Need

## Thermal Exposure

## UL 94 V-0

## Compression

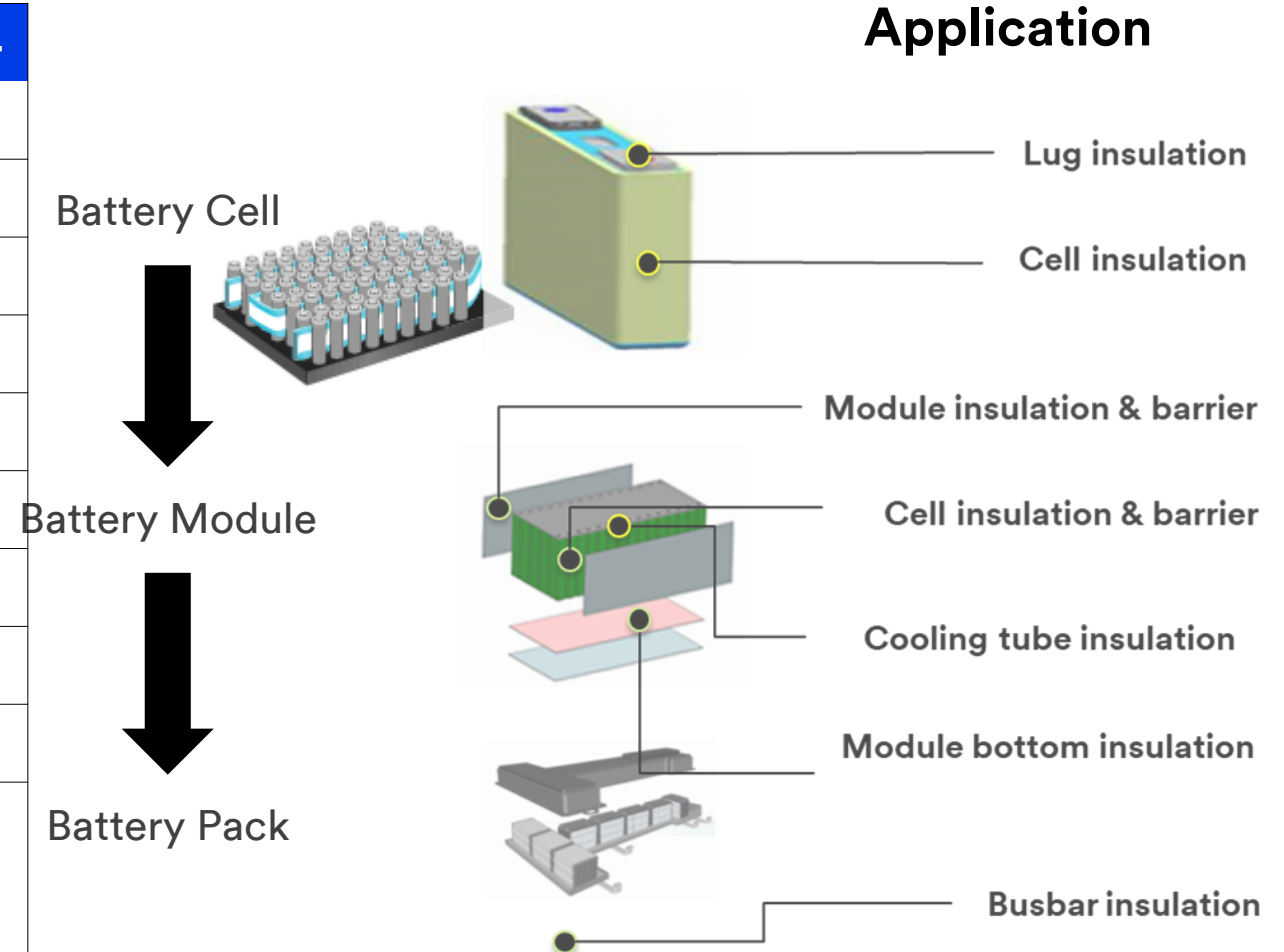

## Shear

e.g. 3M™ TRB600 & TRB1000

# Electrical Properties to Address the Need

Property	3M FRB-NT254
Dielectric strength	5.0 kV
UL 94 flame rating	V-0 and 5VA
High voltage arc tracking rate (HVTR)	PLC = 0
Comparative Tracking Index (CTI)	PLC = 0
High current arc to ignition (HAI)	PLC = 2
Hot wire ignition	PLC = 4
Glow wire ignition temperature (GWIT)	990°C
Glow wire flammability index (GWFI)	960°C
High volt, low current arc resistance	PLC = 4
Relative thermal index, component <ul style="list-style-type: none"> <li>• Electrical</li> <li>• Mechanical</li> </ul>	140°C 130°C

# Learning From the Past to Help With the Future

The automotive industry is going through a tremendous change, but change is not new

To meet these challenges it is important that to gain a deep understanding of the fundamental material properties and how those translate to the application

Representative, application specific test development can help the industry move at the speed needed to meet this challenge

Battery safety is a complex challenge that requires addressing thermal, mechanical, electrical and chemical needs

**By thinking of battery safety at a system level innovative solutions that help address safety challenges while still balancing cost and complexity can be developed.**

**Thank you!**

**Technical Information:** The technical information, guidance, and other statements contained in this document or otherwise provided by 3M are based upon records, tests, or experience that 3M believes to be reliable, but the accuracy, completeness, and representative nature of such information is not guaranteed. Such information is intended for people with knowledge and technical skills sufficient to assess and apply their own informed judgment to the information. No license under any 3M or third party intellectual property rights is granted or implied with this information. **Product Selection and Use:** Many factors beyond 3M's control and uniquely within user's knowledge and control can affect the use and performance of a 3M product in a particular application. As a result, customer is solely responsible for evaluating the product and determining whether it is appropriate and suitable for customer's application, including conducting a workplace hazard assessment and reviewing all applicable regulations and standards (e.g., OSHA, ANSI, etc.). Failure to properly evaluate, select, and use a 3M product and appropriate safety products, or to meet all applicable safety regulations, may result in injury, sickness, death, and/or harm to property. **Warranty, Limited Remedy, and Disclaimer:** Unless a different warranty is specifically stated on the applicable 3M product packaging or product literature (in which case such warranty governs), 3M warrants that each 3M product meets the applicable 3M product specification at the time 3M ships the product. 3M MAKES NO OTHER WARRANTIES OR CONDITIONS, EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, ANY IMPLIED WARRANTY OR CONDITION OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, OR ARISING OUT OF A COURSE OF DEALING, CUSTOM, OR USAGE OF TRADE. If a 3M product does not conform to this warranty, then the sole and exclusive remedy is, at 3M's option, replacement of the 3M product or refund of the purchase price. **Limitation of Liability:** Except for the limited remedy stated above, and except to the extent prohibited by law, 3M will not be liable for any loss or damage arising from or related to the 3M product, whether direct, indirect, special, incidental, or consequential (including, but not limited to, lost profits or business opportunity), regardless of the legal or equitable theory asserted, including, but not limited to, warranty, contract, negligence, or strict liability.
